INSTRUCTION MANUAL

QJR type

Quick Jaw Replacement Power Chuck

DANGER

- This instruction manual is for production engineers and maintenance personnel in charge of operation of this product. When a beginner uses this product, receive instructions from experienced personnel, the distributor or our company.

- Before installing, operating or maintaining this equipment, carefully read this manual and the safety labels attached to the equipment. Failure to follow these instructions and safety precautions could result in serious injury, death, or property damage.

- Store this manual near equipment for future reference.

- If any questions related to safety arise about this manual, please confirm them with the distributor or our company.

KITAGAWA IRON WORKS CO., LTD.

77-1 Motomachi, Fuchu, Hiroshima 726-8610 Japan
TEL +81-(0)847-40-0526
FAX +81-(0)847-45-8911
Preface

This manual provides detailed information about how to safely and correctly use the power chuck (QJR type) for a lathe.

Before starting to use this power chuck, read this manual carefully and always follow the instructions and warnings in "Important Safety Precautions" and "Precautions for Use" at beginning of the manual. Failure to follow these precautions could result in a serious accident.

Terms and Symbols Used for Safety Messages

In this manual, precautions for handling that are considered especially important are classified and displayed as shown below depending on the damage of risk including the seriousness of the harm that could result. Please sufficiently understand the meanings of these terms and follow the instructions for safe operation.

⚠️ Safety Alert Symbol

The triangle is the safety alert symbol used to alert you to potential safety hazards that could result in injury or death.

⚠️ DANGER

Indicates a hazardous situation which, if you not avoided, will result in death or serious injury.

⚠️ WARNING

Indicates a hazardous situation which, if you not avoided, could result in death or serious injury.

⚠️ CAUTION

Indicates a hazardous situation which, if you not avoided, could result in minor or moderate injury.

⚠️ NOTICE

Indicates instructions which, if not avoided, could result in damage to the equipment or a shortened work life.
Liability and How to Use this Manual

This product is suitable for gripping a workpiece on the lathes or rotary tables. This product is equipped with the jaws to clamp the workpiece and they operate by means of a rotary cylinder. For any other applications, please contact us. Our company will not assume responsibility for injury, death, damage, or loss resulting from not following the instructions in this manual.

There are countless things that cannot or should not be done, and it is impossible to cover all of them in this manual. Therefore, do not perform any actions unless they are specifically allowed in this manual. If any questions related to safety arise about operation, control, inspection and maintenance which are not specified in this manual, please confirm them with our company or distributor before performing them.

Guarantee and Limitation of Liability

The guarantee period of this product is 1 year after delivery. Use the parts delivered by Kitagawa Iron Works for all the parts including consumable parts. We will not assume responsibility for injury, death, damage, or loss caused by usage of parts not manufactured by Kitagawa Iron Works. Additionally, if parts other than genuine parts manufactured by Kitagawa Iron Works are used, this guarantee will be completely invalid.

The chuck and cylinder from Kitagawa Iron Works should be used together. If you must use a part not made by Kitagawa, check with us or our distributor to be sure it is safe to do so. We will not be responsible for injury, death, damage or loss caused by use of a chuck or cylinder made by another company unless this use has been approved by Kitagawa or its distributor.

1-3. Scope of product

This instruction manual is for the chuck part.

- To prevent the work from flying, safe design, maintenance and erroneous action prevention of the hydraulic system to maintain the gripping force of the chuck is extremely important. Thoroughly read the “Important Safety Precautions” on and after page 8 in this manual.
- As for the cylinder, follow the instruction manual for the cylinder.

2. Important Safety Precautions

Important safety precautions are summarized below. Please read this section before first starting to use this product.

**DANGER** Failure to follow the safety precautions below will result in serious injury or death.

Turn off main power supply before attaching, inspecting or replacing chuck, and before adding oil.

- The chuck may start rotation suddenly, and a part of the body or clothing may be caught.

Close door before rotating spindle.

- If the door is not closed, you may touch the rotating chuck or the work may fly out, which is very dangerous. (In general, the safety interlock function which allows rotation only when the door is the manual mode or the test mode)

During spindle rotation, do not turn off hydraulic pump power supply and do not operate switching valve.

- Cutting off hydraulic pressure causes a drop in the gripping force which could result in the work being released and flying out.
- Operating the manual switching valve or solenoid valve will lead to a drop of hydraulic pressure.
DANGER  Failure to follow the safety precautions below will result in serious injury or death.

Do not allow the rotation speed of the chuck to exceed the maximum allowable speed limit. (Refer to pages 16-23)

- If the rotation speed of the chuck exceeds the rotation speed limit, this is very dangerous as the chuck and work will fly out.

The input force of the chuck (piston thrust, pulling force of the draw pipe) must not exceed the allowable maximum input force. (Refer to pages 16-23)

- Input must match the specification of the chuck.
- Adjust the hydraulic pressure to the cylinder so that the input force, which determines the gripping force of the chuck, does not exceed.
- Excessive input force can lead to breakage of the chuck, which is very dangerous, as the chuck can work can be damaged and fly out.
Important Safety Precautions

**DANGER** Failure to follow the safety precautions below will result in serious injury or death.

Keep the height of the jaw within the range specified in the gripping force limit table (Refer to pages 20-23). If you must use a jaw taller than a standard soft jaw, use less than the input (piston thrust force, draw pipe drawing force) specified in the gripping force limit table. 

For All Users

- Do not use a jaw of a height out of the range of the gripping force limit table or a jaw with mass moment out of the range of the gripping force limit table. The chuck will break and the chuck and work will break and fly out.

When the protrusion of the work is long, support it with the steady rest or center.

For All Users

- If the protrusion is long, the tip of the work can turn and the work fly out.

Determine the gripping force required for processing by the machine tool manufacturer or user, and check that the required gripping force is provided before processing. (Refer to pages 16-23 and cylinder manual)

For All Users

- Adjust the hydraulic pressure to the cylinder to obtain the required gripping force. If the gripping force is insufficient, this is dangerous as the work will fly out.
Important Safety Precautions

DANGER
Failure to follow the safety precautions below will result in serious injury or death.

Use of a chuck and cylinder that cannot be used together safely may cause the cylinder to break at high pressure resulting in the chuck and work flying out.

- Check that the chuck and the cylinder are in the “safe combination” when using at high pressure with our company or the distributor. Especially when the cylinder of our company and a high pressure chuck of other company are combined, confirmation is necessary.
- If one of the abnormal events shown below occurs during operation, immediately stop the machine and consult with our company or the distributor.
  - The work slips.
  - Loss of accuracy.
  - The work begins to chatter.
  - The machine’s vibration significantly increases.
  - The gripping force does not rise even if hydraulic pressure is raised.

In the case of processing a significant unbalanced work, lower the rotation speed.

- Unbalanced work generates dangerous centrifugal forces and the work could fly out.
Important Safety Precautions

DANGER Failure to follow the safety precautions below will result in serious injury or death.

Always tighten the bolts at the specified torque. If the torque is insufficient or excessive, the bolt will break, which is dangerous as the chuck or work will fly out. Use the bolts attached to the chuck, and do not use bolts other than these.

- If the torque is insufficient or excessive, the bolt will break, which is dangerous as the chuck or work will fly out.
- Fix the lathe spindle or the chuck when you tighten bolts. Your hand could slip and get injury when you work without fixing the spindle.
- You cannot control the torque by a hex key. You must use a torque wrench for torque control.
- When you join soft jaws to base jaws, you tighten the bolts at the torque in ( ).

### Specified torque for socket head cap screw

For All Users

\[
F = 127 \text{ (N)} \quad (13 \text{ kgf})
\]

\[
T = F \times L
= 127 \times 0.1
= 12.7 \text{ (N·m)}
\]

- Tightening torque is moment of force when you tighten a bolt. Tightening torque= \( F \times L \).
Important Safety Precautions

**DANGER**
Failure to follow the safety precautions below will result in serious injury or death.

Provide sufficient strength for the draw pipe (Refer to pages 43-45).
Provide sufficient screw depth for the draw pipe.
Firmly tighten the draw pipe.

- If the draw pipe breaks, the gripping force is instantly lost and this is dangerous as work will fly out.
- If the screw depth of the draw pipe is insufficient, the screw will break and the gripping force will be lost instantly, and this is dangerous as work will fly out.
- If the engagement of the screw of the draw pipe is loose, vibration may occur resulting in breakage of the screw. If the screw breaks, the gripping force will be lost instantly, which is dangerous as the work will fly out.
- If the draw pipe is unbalanced, vibration occurs, the screw is broken and the gripping force will be lost instantly, which is dangerous as the work will fly out.

**Use a cylinder with a lock valve (safety valve, check valve) incorporated in case of sudden hydraulic pressure drop due to blackout, malfunction of the hydraulic pump, etc. Further, use a solenoid valve with a circuit that retains the gripping position when no current is carried.**

- If the hydraulic pressure suddenly drops due to blackout or malfunction of the hydraulic pump, etc., this is dangerous as work will fly out.
- Lock valve retains the hydraulic pressure inside the cylinder temporarily, when the hydraulic pressure suddenly drops due to blackout or malfunction of the hydraulic pump, etc.
Important Safety Precautions

⚠️ **WARNING** Failure to follow the safety precautions below could result in serious injury or death.

Do not modify the chuck.

- It may not only break the chuck but the chuck and the work may fly out, which is dangerous.
- If you attach a locator or jig on the chuck, use the taps of the chuck surface. (Refer to page 34).

Periodically supply adequate grease (Refer to page 35-36). Turn off power before adding grease.

- Insufficient grease supply lowers the gripping force, causes operation failure due to lower hydraulic pressure, lowers the gripping precision, and causes abnormal wearing and seizing, etc.
- This is dangerous as the work could fly out from a drop in the gripping force.

Do not operate the machine after drinking alcohol or taking medication.

- Dangerous since these lead to operation mistakes and misjudgment.

Do not operate the machine wearing gloves, a necktie, and other loose clothing or jewelry.

- Dangerous since it will be caught.

Do not grip a chuck with a chuck.

- Because it is easy to confuse the specifications of each chuck and the protrusion become long and is apt to raise rotation speed, it is apt to exceed the specifications of the base chuck. The chuck may break and the chuck or work could fly out.

When storing this product, the product should be subjected to the antirust treatment and stored in a place free from wetting, condensation, or freeze.
3-2. Relationship between gripping force and rotation speed

1. Maximum static gripping force
The static gripping force is the gripping force when the chuck is at a stop.
The power chuck has a mechanism to convert input force (piston thrust force, draw pipe drawing force) from the cylinder to gripping force. Therefore, the gripping force when the allowable maximum input force becomes the maximum static gripping force. However, the gripping force is different depending on the state of grease lubrication, grease in use, height of the jaw, etc. The maximum static gripping force specified in the specification is the value under the following conditions:
• The Kitagawa standard soft jaw is used as the jaw.
• The attaching bolts of the soft jaw are tightened at the specified torque.
  (Refer to page 25)
• The numerical values are obtained with the Kitagawa gripping force meter. The gripping position of the gripping force meter is at a position 1/2 of the height of the soft jaw.
• CHUCK GREASE PRO is used. (Refer to page 35).
• A variable displacement pump with the discharge volume of 20 liters/min or more is used as the hydraulic source. The pressure is set by the pressure control equipment of the pump itself, or the pressure reduction valve equipped separately.

![Fig.5](image-url)
2. Allowable maximum rotation speed

In the case of outside diameter gripping, when the chuck is rotated, the gripping force lowers due to the centrifugal force of the top jaw. Therefore, the rotation speed when the dynamic gripping force (gripping force during rotation) becomes approximately 1/3 of the maximum static gripping force is set as the allowable maximum rotation speed. The centrifugal force is different depending on the mass of the top jaw and the barycentric position as well as the rotation speed. The allowable maximum rotation speed specified in the specification is the value under the following conditions:

- The Kitagawa standard soft jaw is used.
- The base jaw and soft jaw are attached to the position refer to Fig.6.
- Grip the gripping force meter in the center of the jaw stroke, and at this point, the base jaw is attached at the position where the periphery side end of the base jaw and the chuck periphery are almost lined up.
- The numerical values are obtained by the Kitagawa gripping force meter. The gripping position of the gripping force meter is at a position 1/2 of the height of the soft jaw.

![Fig.6](image)

To avoid serious accidents caused by the chuck or work flying out:

- Determine the gripping force required for processing by the machine tool manufacturer or user, and check that the required gripping force is provided before processing. The gripping force of the chuck must not exceed the maximum static gripping force.
- Determine the rotation speed required for processing by the machine tool manufacturer or user based on the gripping force required for the processing. The rotation speed at this point must not exceed the allowable maximum rotation speed.
When determining the cutting conditions, consider about the reducing gripping force by the centrifugal force and the limitation of the gripping force by gripping height.

Pay attention since the gripping force is different depending on the state of the oil supply, grease in use, height of the jaw, performance of the pump and the pressure reducing valve, piping state, etc.

3. **Relationship between gripping force and rotation speed**

As the rotation speed becomes higher, the centrifugal force of the jaw increases and the gripping force lowers. The curves displayed in Fig.7 shows relationships between the rotation speed and the centrifugal force when using the base jaw and the standard soft jaw which are not exceeding outer diameter of chuck. The centrifugal force differs significantly depending on the size and shape of the top jaw and the base jaw attaching position, therefore, when the rotation speed is high, actual measurement using a Kitagawa gripping force meter is required.
• In the case of processing a considerably unbalanced work, lower the rotation speed. The work will fly out and this is dangerous.

• Vibration is generated if there is unbalance due to the work and the jig, etc. Vibration decreases process precision and shortens the working life of the chuck, even possibly breaking it. Correct the unbalance by using a balance weight, etc., or lower the rotation speed for use.

• In the case of heavy cutting at high rotation speed, vibration is easily generated in the same manner as the unbalance of the chuck, therefore, set the cutting conditions appropriate for the dynamic gripping force and machine rigidity.
3-3. Relationship between gripping part center height, static gripping force and input force / Relationship between top jaw mass moment and gripping force loss

If the gripping part center height of the used top jaw (dimension H in Fig. 8) is higher than the gripping part center height of the standard soft jaw, a large load is applied to the base jaw, jaw attaching bolts, etc. To prevent these parts from being broken, it is necessary to use the machine by using a lower input force than the allowable maximum input force. Additionally, if the top jaw is larger and heavier, the centrifugal force generated at the top jaw will increase. It is necessary to examine the dynamic gripping force considering the centrifugal force and to use the machine at a rotation speed that can withstand the cutting force.

G: Center of mass of the top jaw
m: Mass of the top jaw
r: Distance from the center of mass of the top jaw to the chuck center
H: Gripping center height

Fig.8

- Keep the height of the top jaw within the range of the gripping force limit table. (Refer to Fig.9)
- If a top jaw is taller than the standard soft jaw, use it at the input force (piston thrust force, draw pipe drawing force) specified in the gripping force limit table. If it is used without lowering the input, the chuck will break and this is dangerous as the chuck and work will fly out.
Fig.9-1
Fig. 9-2
Analysis of the gripping force, input force and rotation speed using Fig. 9, is carried out as shown below.

About ① and ② of a Fig 9, positions when a base jaw is attached to the body differ.

① Base jaw is attached at the position where the periphery side end of the base jaw and the chuck periphery are almost lined up.
② Base jaw is attached to a body outermost position.

The graph of ② is used for the body outermost position for base jaw at attachment.

• For example, in the case of QJR08, when base jaw is attached at the position where the periphery side end of the base jaw and the chuck periphery are almost lined up (Refer to Fig.9-1-①). Standard soft jaw (mass moment 156kg·mm), it cannot exceed 5000min⁻¹ (rpm), and the gripping force loss due to the centrifugal force at this rotation speed is 66kN. The required static gripping force for the dynamic gripping force (gripping force loss by static gripping force - centrifugal force) to become 1/3 of the static gripping force is 100kN, and the required input to obtain this gripping force is 45kN. However, it is necessary to use at the gripping part center height H=25 mm or less.

In the case of QJR08, when base jaw is attached to a body outermost position(Refer to Fig.9-1-②). Standard soft jaw (mass moment 210kg·mm), it cannot exceed 4200min⁻¹ (rpm),

• If the gripping part center height H is high, it is necessary to lower the static gripping force.
• If the top jaw mass moment is large, the rotation speed needs to be lowered.
• If the rotation speed is high, the gripping force loss due to the centrifugal force becomes large. The centrifugal force is proportional to the square of the rotation speed.

The required static gripping force and input force required at the rotation speed in use are predicted from Fig.9, however, it contains a number of hypothetical conditions. Therefore, it is necessary to only use these as reference, and the processing conditions must be determined after trial cutting without fail.
4. Attaching Base jaws and Forming Soft jaws

Always use original base jaws. Other manufacture’s base jaws will be cause to damage of the chuck.

4-1. Joining soft jaws to base jaws

**DANGER**

- Be sure to use the attached bolts. In an unavoidable case, use the bolt of strength 12.9 (M22 or more, 10.9) or more and sufficient length.
- Never start the spindle when attaching bolts have been loosing. The top jaws will discharge.
- Always tighten the bolts at the specified torque. If the torque is insufficient or excessive, the bolt will break, which is dangerous as the chuck or work will fly out.

<table>
<thead>
<tr>
<th>Bolt size</th>
<th>Tightening torque</th>
<th>Depth of tap (Base-jaws)</th>
</tr>
</thead>
<tbody>
<tr>
<td>QJR07</td>
<td>M10 40N•m</td>

<td>M12 70N•m</td>
<td>20mm</td>
</tr>
<tr>
<td>QJR12</td>
<td>M16 170N•m</td>
<td>26mm</td>
</tr>
</tbody>
</table>

**CAUTION**

- Base jaw is distorted, if you tighten the bolts for joining soft jaw to base jaw at the excessive torque.

**NOTICE**

- When attaching top jaw to base jaw, base jaw remove from body.
4-2. Replacing base jaws

Make stroke to open position of the chuck when replacing base jaws. Insert the wrench to lock pin and rotate it to direction toward OFF then take off the base jaws (Refer to the following). Clean and lubricate the sliding surface when replacing base jaws.

![Diagram showing lock pin position, wrench, stroke mark, stroke range, and insertion range.]

**WARNING**

- If moving chuck while process of replacing base jaws, it will be cause of breaking the chuck.
- If rotate lock pin while stroke to close position of the chuck, it will be cause of breaking the chuck.

**NOTICE**

- Hold base jaw and soft jaw while process of replacing them, because there is a danger of injury or damage if they fall down by the weights of themselves.
• Check that the reference mark on the side of the base jaw is within the stroke range. Full stroke the jaws at least once a day to check it before work or when replacing base jaws. If it goes out of the stroke range due to loosening of the draw nut, etc., the work may not be gripped, and this is dangerous as the work will fly out.

• When gripping the work, use it by keeping the position within the appropriate stroke range. Gripping in the center of the stroke is the most stable for the mechanism, and the best precision can be obtained.
  • When gripping near the stroke end or stroke start, the work may not be gripped sometimes according to the deviation, etc., of the gripping part allowance of the work, and this is dangerous as the work will fly out.
  • When gripping near the stroke end or stroke start, the chuck may break and the chuck or work could fly out.

5. Usage

This product is a device to fix a work-piece when it is processed by the lathe machine or the rotary table.

The rotary cylinder closes the jaw and fixes a work-piece so that it does not move during processing. The chuck opens the jaw after having processed it and remove a work-piece.

**NOTICE**

- When replacing the base jaws, carefully clean the sliding surface of the body and the base jaws. Failure to do this may cause a precision failure.
- Set the hydraulic pressure according to the shape of the work and the cutting conditions. Pipe shape work, etc., may be distorted if they are tightened at a high gripping force.

5-1. Precautions during gripping work with chuck

**DANGER**

- When gripping a work with the chuck, do not get fingers or hands become caught. This could cause crushed or cut fingers and hands.

5-2. Precautions during gripping work in irregular shape

**DANGER**

- Cast metal, pitched shape or taper shape cannot be gripped.
- If the protrusion of the work is long, support it with a center or the steady rest. If the protrusion is long the tip of the work turns, and this is dangerous as the work will fly out.
5-3. Precautions related to usage of jaw

- If a base jaw other than one made by Kitagawa Iron Works is used, the engagement will be inferior, and the master jaw will be deformed, the gripping precision will worsen, and the work will fly out due to gripping failure, which is dangerous.

- If a soft jaw other than one made by Kitagawa Iron Works is used, the engagement will be inferior, and the base jaw will be deformed, the gripping precision will worsen, and the work will fly out due to gripping failure, which is dangerous.

- Do not use a top jaw with a different serration pitch from the base jaw. The engagement of the crests of the serration will become insufficient, therefore, the serration crests will break when gripping the work, and this is dangerous as the jaw and work will fly out.

- Do not use the soft jaw by welding to join for extension. The jaw will break due to insufficient strength and the serration part will become distorted due to welding. As a result, the engagement will worsen, the serration crests will break, and this is dangerous as the work will fly out.
5-4. Precautions related to processing

<1> Unbalance

- In the case of processing largely unbalanced work, lower the rotation speed. The work will fly out and this is dangerous.
- Vibrations are generated if there is unbalance owing to the work or the jig, etc. Vibration not only will impart a negative influence on the process precision but also the endurance of the chuck being remarkably shortened, and the chuck may break. Correct the unbalance using balance weights, etc., or lower the rotation speed for use.
- Heavy cutting at high rotation speed easily generates vibration in the same manner as chuck unbalance, therefore, set cutting conditions appropriate for the dynamic gripping force and machine rigidity.

<2> Interference, contact, impact

- Before starting work, check that the top jaw, locator, work, etc., and the tool and the tool post, etc., do not interfere at low rotation and then start processing.
- Do not allow anything to impact the chuck, jaw, and the work. The chuck will break and this is dangerous as the chuck and work will fly out.
- If the tool and the tool post contact the chuck or the work due to malfunction or tape mistake, etc., and impact is given, immediately stop the rotation, and check that there are no abnormalities in the top jaw, base jaw and bolts of each part, etc.

<3> Coolant

- Unless coolant with a rust preventive effect is used, rust will occur inside the chuck and gripping force drop may result. The work will fly out due to the gripping force drop and this is dangerous.
5-5. Attachment of locator and jig

- In the case of attaching the locator and the jig on the chuck surface, use the taps specified in Fig. 11.

Fig. 11

</tbody>
</table>

- The chuck can not be modified. This will not only break the chuck but the chuck and work may fly out, which is dangerous.
- Attach the locator or the jig with bolts which have sufficient strength due to centrifugal force. The locator or the jig may fly out, and this is dangerous.
6. Maintenance and Inspection

6-1. Periodic Inspection

- Clean and lubricate the sliding surface when replacing the base jaws.
- Add grease at least once a day.
- Fully stroke the jaw before starting work or upon supplying grease, and check that the jaw is inside the appropriate stroke area. (Refer to page 26)
- Always clean the chuck body or the sliding surface using an air gun, etc., at the end of work.
- Check that the bolts of each part are not loosened at least once every 3 months.
- Disassemble and clean at least once every 6 months or every 100,000 strokes (once every 2 months or more for cutting cast metal).

6-2. Grease lubrication

1. Position to lubricate

- Lubricate using a grease gun from the grease nipple on the rear body periphery part.
- Supply the grease both times when the jaws are opened and closed.
- After lubrication, repeat opening and closing the jaw several times without gripping work.

2. Grease to use

- Use the designated grease specified in Table 5. If grease other than the designated grease is used, sufficient effect may not be obtained.

<td>Kluberpaste ME31-52</td>
<td>Kluber lubrication (worldwide)</td>
</tr>
</tbody>
</table>
3. Frequency of lubrication

- Lubricate the sliding surface when replacing the base jaws.
- Add grease at least once every day.

**NOTICE**

- Lubricate same volume each jaw. Difference will be cause of the unbalance.
- Add approximately 2-4g up to 8 inches and 4-8g for 10 inches or larger of grease to the each jaw.
- In the case of high rotation or in the case of using a large amount of water soluble cutting oil, increase the frequency of lubrication according to the usage conditions.

**WARNING**

- To keep the chuck running in the best condition for a long time, adequate grease lubrication is necessary. Insufficient grease lubrication causes a drop in the gripping force, operation failure at low hydraulic pressure, drop in gripping precision, abnormal wearing, seizing, etc. The work will fly out due to a drop in the gripping force and this is dangerous.

4. Safety information about grease and anti-rust oil

**Applicable range**

- Designated grease
- Antirust agent applied to the product at the delivery.

**First aid measures**

After inhalation: Remove victim to fresh air. If symptoms persist, call a physician.
After contact with skin: Wash off with mild cleaners and plenty of water. If symptoms persist, call a physician.
After contact with eyes: Rinse with plenty of water. If symptoms persist, call a physician.
After ingestion: If large amounts are swallowed, do not induce vomiting. Obtain medical attention.

Please refer to each MSDS about the grease and the anti-rust oil which you prepared.
6-3. Disassembling

Disassembling procedures
1. Turn off the main power of the machine before starting work.
2. Remove the base jaws[3].
3. Turn the draw nut [6] with the handle [13] while loosening the chuck attaching bolt [17], and remove the chuck from the spindle.
   Use an eyebolt or a hanging belt when attaching and detaching the chuck to and from the machine.
4. Remove the rear body[2] while loosening the socket head cap screws[16].
   QJR08&10 have the tap for disassembling on the rear body.
   QJR12 has the connecting bolts from the front of body.
5. Take off the guide pins[10] and remove the lock pins[9].
   When removing lock-pin and guide-pin,
   be careful to not lose the steel-balls[9-2][10-3].
6. Lift up the plunger[5] and remove the master jaws[4].
7. Remove the plunger guide[8] while loosening the socket head cap screws[15].
8. Assemble again while sufficiently coating the recommended grease in the reverse procedures of disassembling. At this time, pay sufficient attention so as not to make a mistake in the numbers of the body [1], master jaws[4], and the plunger[5].
9. Refer to page 48 about the installation procedure. (8-5. Attachment of chuck).
- Use an eyebolt or a hanging belt when attaching and detaching the chuck to and from the machine, as there is a danger of injury or damage if the chuck drops.

<table>

</thead>
<tbody>
<tr>
<td>7</td>
<td>M8</td>
</tr>
<tr>
<td>8, 10</td>
<td>M10</td>
</tr>
<tr>
<td>12</td>
<td>M12</td>
</tr>
</tbody>
</table>

**WARNING**

- Remove the eyebolt or the belt without fail after using. If the chuck is rotated with the eyebolt, etc., attached, they may fly out and this is dangerous.
- Disassemble and clean the chuck at least once every 6 months or every 100,000 strokes (once every 2 months or more for cutting cast metal). If cutting powder or other substances stagnate inside the chuck, it will lead to insufficient stroke and a drop in the gripping force, and this is dangerous as the work will fly out. Check each part carefully and replace any part that is worn or cracked.
- After inspection, apply sufficient grease in the designated areas and reassemble.
- After assembling, measure the gripping force according to the method on page 16, and check that the specified gripping force is obtained.
- If you stop the machine for a long period of time, remove the work from the machine. If you don’t, the work can drop due to a drop in the hydraulic pressure or the cylinder can stop or malfunction.
- If you stop the machine or store the chuck for a long period of time, add grease to prevent rust.
## 7. Malfunction and Countermeasures

### 7-1. In the case of malfunction

Check the points specified in the table below and take the appropriate countermeasure.

<table>
<thead>
<tr>
<th>Defective</th>
<th>Cause</th>
<th>Countermeasure</th>
</tr>

<td>The sliding surface is seized.</td>
<td>Disassemble, correct the seized part with oilstone, etc., or replace the part.</td>
</tr>
<tr>
<td></td>
<td>The cylinder is not operating.</td>
<td>Check the piping and the electric system, and if there is no abnormality, disassemble and clean the cylinder.</td>
</tr>
<tr>
<td>Insufficient stroke of the jaw.</td>
<td>A large amount of cutting powder is inside.</td>
<td>Disassemble and clean.</td>
</tr>
<tr>
<td></td>
<td>The draw pipe loosened.</td>
<td>Remove the draw pipe and retighten it again.</td>
</tr>
<tr>
<td></td>
<td>The stroke of the jaw is insufficient.</td>
<td>Adjust so that the jaw is near the center of the stroke when gripping the work.</td>
</tr>
<tr>
<td></td>
<td>The gripping force is insufficient.</td>
<td>Check that the correct hydraulic pressure is obtained.</td>
</tr>
<tr>
<td></td>
<td>The forming diameter of the top jaw is not consistent with the work diameter.</td>
<td>Form again based on the correct forming method.</td>
</tr>
<tr>
<td></td>
<td>The cutting force is too large.</td>
<td>Calculate the cutting force and check that it is suitable for the specification of the chuck.</td>
</tr>
<tr>
<td>Insufficient grease lubrication</td>
<td></td>
<td>Supply grease from the grease nipple and lubricate the sliding surface, then open and close the jaw several times without gripping a work.</td>
</tr>
<tr>
<td></td>
<td>The rotation speed is too high. Swinging occurs due to incorrect alignment of cores of work feeder, steady rest, tail stock, etc.</td>
<td>Lower the rotation speed to a speed at which the required gripping force can be obtained. Align the cores sufficiently to eliminate such swinging.</td>
</tr>
<tr>
<td>The Work slips.</td>
<td>The outer periphery of the chuck is running out.</td>
<td>Check the end surface run-out and the outer periphery, and retighten the chuck attaching bolts.</td>
</tr>
<tr>
<td></td>
<td>Dust is attached on the sliding surface.</td>
<td>Clean and lubricate the sliding surface.</td>
</tr>
<tr>
<td></td>
<td>The attaching bolt of the top jaw is not tightened sufficiently.</td>
<td>Tighten the top jaw attaching bolt at the specified torque. (Refer to page 25)</td>
</tr>
<tr>
<td></td>
<td>The forming method of the soft jaw is inappropriate.</td>
<td>Is the plug for forming parallel to the chuck end surface? Is the plug forming not deformed due to the gripping force?</td>
</tr>
<tr>
<td></td>
<td>The height of the top jaw is too high, the top jaw is deformed, the top jaw attaching bolt is elongated.</td>
<td>Lower the height of the top jaw. (Replace it with the standard size) or check the gripping contact surface and make it uniform.</td>
</tr>
<tr>
<td></td>
<td>The gripping force is too large leading to the work being deformed.</td>
<td>Lower the gripping force in the range possible to process to prevent deformation.</td>
</tr>
</tbody>
</table>

---

Table 6
40

7-2. Where to contact in the case of malfunction

In the case of malfunction, contact the distributor where you purchased the product or our branch office listed on the back cover.
For Machine Tool Manufactures

Following pages are described for machine tool manufacturers (personnel who attach a chuck to a machine). Please read following instruction carefully when you attach or detach a chuck to machine, and please sufficiently understand and follow the instructions for safe operation.

8. Attachment

8-1. Outline drawing of attachment

- Attach the manual switching valve at a position where it is easy to operate for the attaching equipment.
- Install the hydraulic unit at a position where the drain hose is not kinked and the needle of the pressure gauge is easily read.
When other actuators are operated by the same hydraulic pressure source as the cylinder for chuck, be sure that a pressure drop of the cylinder does not occur during use. A hydraulic pressure drop leads to a drop in the gripping force which could allow the work to fly out.

- As to the drain hose
  - Use one with inside diameter $\phi 32$.
  - Use a transparent vinyl hose for visualization.
  - Provide a stream slope, without air pocket. This will ensure no back pressure.
  - The end of the hose is physically above the oil level. (Refer to Fig.13)
- If the hydraulic oil stagnates inside the cylinder, oil leakage occurs, which may cause a fire.

- Install after removing the dust inside the pipe completely.
- Add a filter to the pressure supply line. If foreign matters gets inside the cylinder, this is dangerous since the rotation valve of the cylinder will seize, the hose will tear off, and the cylinder will rotate. This is also dangerous as the work will fly out.
- Always use a flexible hose for the hydraulic piping to the cylinder, and the bending force or tensile force of the pipe must not be applied to the cylinder. Use a pipe inside diameter as large as possible and keep the piping length as short as possible.

- Especially, when a large sized hydraulic unit is used, excessive surge pressure is generated and the gripping force becomes large, therefore, it may result in breakage of the chuck or the lowering of endurance. Restrain the surge pressure by adopting a throttle valve, etc.
8-2. Production of draw pipe

Determine the length of the draw pipe as shown below.

The dimension L in Fig.14 is determined from the distance A between the cylinder adapter and the back plate.

At the time of the screw process of the dimension a, the precision is to be JIS 6H and 6h, 6g matching the screw of the piston of the cylinder. Pay attention so that the thread parts on both ends and the inner periphery do not swing or become unbalanced.

</table>
- **Provide sufficient strength for the draw pipe.** If the draw pipe is broken due to insufficiency of the strength, the gripping force will be lost instantly, which is dangerous as the work will fly out.
  - Keep the dimension e and the dimension f in Fig. 14 for the draw pipe and a material with the tensile strength 380MPa or more must be used.
  - The personnel who designed draw pipe must judge whether the strength of the draw pipe is sufficient for the usage conditions.
  - The dimensions and materials specified in this manual do not guarantee that the draw pipe will not break under every usage condition.
- If the screw-in depth of the draw pipe to the draw nut is insufficient, the screw will break and the gripping force will be lost instantly, which is dangerous as the work will fly out.
- If the engagement of the screw of the draw pipe is loose, vibration may occur resulting in breakage of the screw. If the screw breaks, the gripping force will be lost instantly, which is dangerous as the work will fly out.
- **If the draw pipe is unbalanced, vibration occurs,** the screw is broken and the gripping force will be lost instantly, which is dangerous as the work will fly out.
8-3. Processing of draw nut

1. Loosen the set screws(M3)[14], then rotate and remove the nut[7].
2. Remove the draw nut[6].
4. Assemble it again. Tighten surely the nut[7] and the set screws(M3)[14].

**WARNING**

- If the nut is not fastened surely, the draw nut will come loose and the work could fly out.

**WARNING**

- Do not process the draw nut for screw of the dimensions f MAX specified in Table 7 or more. The draw nut may break and the work could fly out.
8-4. Production of back plate

**NOTICE**

- Process the engagement diameter of the back plate after measuring the actual spindle.
- Run-out of the back plate directly affects the process precision. The end surface run-out of the back plate, spigot joint diameter run-out must be 0.005 mm or less.
- The precision of the processing of the chuck attachment end surface of the back plate and the spigot joint diameter can be raised by processing them after mounting to the installed machine.
- Process the chuck attachment spigot joint diameter of the back plate at the target value A-0.01 in the dimension A of Table 8.
- Fig.17 shows the case of the JIS short taper standard.

Dimension A (spigot joint diameter) conforms to the DIN standard.
DANGER

- Always tighten the bolts at the specified torque. If the torque is insufficient or excessive, the bolt will break, which is dangerous as the chuck or work will fly out.
- Use the bolts attached to the chuck, and do not use other bolts. However, if you must use other bolts not provided by Kitagawa, use bolts that have at least a strength classification of 12.9 (10.9 for M22 or more) and be sure they are long enough.

8-5. Attachment of chuck

1. Attaching the draw pipe to the cylinder
   - Apply adhesive onto the screw part of the draw pipe, and screw it into the piston rod of cylinder. At this time, refer to the instruction manual for the cylinder for tightening torque.

   **NOTICE**
   - When attaching the draw pipe to the cylinder, the stopper pin of the piston may break if tightened at the stroke middle position of the piston. In the case of a SS type and S type cylinder, screw it in so that the piston rod is fully out. Follow the explanation of the instruction manual for the cylinder for other items about the cylinder.

2. Attach the cylinder to the spindle (or the cylinder adapter)
   - Check the run-out of the cylinder, and if it is normal, attach the hydraulic pipe.
   - Move 2 to 3 times at low pressure (0.4 MPa-0.5 MPa) and set the piston at the forward end and turn off the power supply.

   **CAUTION**
   - Use an eyebolt or a hanging belt when attaching and detaching the chuck to and from the machine, as there is a danger of injury or damage if the chuck drops.

   **WARNING**
   - Remove the eyebolt or the belt without fail after using. If the chuck is rotated with the eyebolt, etc., attached, they may fly out and this is dangerous.

<table>

</tr>
</tbody>
</table>
3. Connect the chuck to the draw pipe
   • Remove the base jaws, and insert the handle to the chuck center hole, to connect to the draw pipe while turning the draw nut.
   • When connecting the draw nut and the draw pipe, do not forcibly screw them in if they cannot be screwed smoothly, but check the inclination of the core of the screw, etc.

**DANGER**

- If the screw-in depth of the draw pipe to the draw nut is insufficient, the screw will break and the gripping force will be lost instantly, which will the work to fly out.
- If the engagement of the screw of the draw pipe is loose, vibration may occur resulting in breakage of the screw, loss of gripping force and the work flying out.

4. Attach the chuck matching to the attaching surface of the spindle (or the back plate).
   • Turn the handle for connection to make a state that the chuck closely contacts the spindle attaching surface of the lathe.

**NOTICE**

- If draw nut is tightened too much, draw pipe and handle will interference, and handle may separate from the draw nut. After chuck closely contacts the spindle attaching surface of the lathe, do not forcibly screw them, if they cannot be screwed smoothly, tighten a chuck using attaching bolt.

![Fig.18](image)

- In the case of adjusting the centering of the chuck, lightly hit the body side face with a plastic hammer.
- Tighten the chuck attaching bolts evenly. At this time, tighten the bolts at the specified torque. (Refer to page 47)
5. Adjust the position of the plunger

- The appropriate position of the plunger at the cylinder forward end is the position when the clearance of between the plunger and the plunger guide becomes 0.5-0.8mm.
  1. Loosing the draw nut to forward until hitting the body and plunger.
  2. Then screw the draw nut to forward until the position of the notch.
  3. Decide how many should be clicked.
     - The notch are placed on the draw nut each 60°.
     - For example
       - If the thread pitch is 1.5mm, backward distance become to 0.5mm per 2 notch.
       - If the thread pitch is 2.0mm, backward distance become to 0.7mm per 2 notch.
       - If the thread pitch is 2.5mm, backward distance become to 0.8mm per 2 notch.
  4. Insert the wrench into the lock pin and confirm to rotate to direction. (Refer to page 26)

6. Check the run-out of the chuck

- Keep the periphery run-out and the end surface run-out of the chuck at 0.02mm T.I.R or less.
- Put into the base jaws and confirm the stroke is enough or not (Refer to page 26-27).
  - If the lock pin can not be rotated, adjust the position of the plunger again.
9. Other information

9-1. About standards and orders

This product is based on the following standards or orders.

- Machinery directive:2006/42/EC Annex I
- EN ISO 12100:2010

9-2. Information about markings of product

Fig.19
9-3. About disposal

Ultimate disposal of this product should be handled according to all national laws and regulations.
